## SECTION 1

## SUMMARY

## 1.1 ACCEPTABILITY

Hexagon Sensor Subsystem S/N 015, intended to be used as the payload in SV-12, was accepted for delivery on 26 September 1974.

The resolving capability of both cameras at all collimator positions and at all test temperatures exceeds the performance requirements. An on-orbit performance prediction, using camera-measured values, is a resolution (at nadir at 70°F) of 192 cycles/mm for the FWD-looking camera and 188 cycles/mm for the AFT-looking camera. These predictions closely agree with the corrected peak mean resolution measurements at nadir at 70°F in Chamber A of 187 cycles/mm for the FWD-looking camera and 190 cycles/mm for the AFT-looking camera.

The measured color resolving capability of both cameras at nadir at 70°F was 118 cycles/mm or better, a performance comparable to the color performance of previous models.

The system's film-to-image synchronization performance met the performance requirements for all collimator positions, applicable temperatures, and operating speeds with the following three exceptions:

<u>Camera</u>	<u>Vx/h</u>	<u>Value</u>	<u>Amount Out of Spec</u>
FWD (A)	0.052	CT/0° - Mean @ 93°F	0.004 ips
AFT (B)	0.036	IT/0° - 2σ @ 70°F	0.005 ips
AFT (B)	0.036	IT/45° - 2σ @ 70°F	0.015 ips

The on-orbit performance prediction for the FWD camera at 0° scan angle and 0° field position at 93°F is 178 cycles/mm; the prediction for the AFT camera at 0° scan angle and 0° field position at 70°F is 188 cycles/mm; the prediction for the AFT camera at 45° scan angle and 0° field position at 70°F is 185 cycles/mm.

## 1.2 ACCEPTANCE TEST HISTORY

The standard test flow used for acceptance testing a Sensor Subsystem is shown in Figure 1-1 including the MFN (manufacturing flow number) and the designation of each test. The chronological testing sequence for Sensor Subsystem S/N 015, given in Table 1-1, includes highlights of significant deviations from the standard test flow. The major deviations, in turn, are described in Paragraphs 1.2.1 through 1.2.3.

MFN = MANUFACTURING FLOW NUMBER

### 1.2.1 Pre-Acceptance Testing

Pre-acceptance testing was highlighted by a FWD side tracking investigation, a malfunction when the film was broken in both FWD and AFT paths, and the resultant rework and retest associated with this malfunction. Initial MFN 3.05 testing showed FWD side tracking to be unsatisfactory. The AFT steerer was found to be defective and was fixed, but tracking remained marginal on short scan runs. It was decided at this point to conduct a preliminary photo test prior to the scheduled platen removal for the shutter spring retrofit (ECO 11830).

During the final run of this chamber test an incorrect command caused the system to behave uncontrollably, breaking the film in both paths (MR 5477). Due to the possibility of damage, all film path elements (rollers, drive rollers, air bars, seal doors) were tested and where necessary adjusted, re-aligned, or replaced. During this rework, the platen shutter springs were retrofitted. When the system was rebuilt, both sides tracked satisfactorily and the system proceeded into acceptance test.

### 1.2.2 Acceptance Testing

Acceptance testing was completed with minimum interruption. Only two anomalies occurred: (1) 100 Hz oscillation on fwd output film drive (MR 5494) and (2) take-up fwd builder roller failure (MR 5499). Troubleshooting and repair of both anomalies was routine.

### 1.2.3 Post-Acceptance Testing

After acceptance testing, the Customer gave direction to proceed with a test plan for the evaluation of SO-208 UUTB (ultra ultra thin base) film. The supply was reloaded with stacks containing 20,000 feet of SO-208, tracking tests with normal (type 1414) film were conducted first and then the transition to SO-208 was made, and tracking was evaluated.

Tracking with SO-208 film proved to be unsatisfactory and further testing on this flight system was deemed inadvisable. The film stacks were then downloaded and transferred to the development model. The supply was reloaded, tracking verified, and the midsection was prepared for shipment.

TE 0515

### 1.3 PERFORMANCE SUMMARY

#### 1.3.1 Optical Bars

Both optical bars passed the pre- and post-vibration Modulation Transfer Function (MTF) at 70°F and at 93°F, but the FWD OB failed the MTF specification at 47°F. Both OBs passed the flange focal length specification, but the AFT OB failed the passive focus shifts at 47°F. The Chamber A performance prediction based on Chamber D data and budgeted errors, however, indicates good performance (See Table 1-2).

TABLE 1-2

PREDICTED AVERAGE RESOLUTION (cycles/mm at 47°F)

Field Angle (Degrees)	FWD Camera		AFT Camera	
	Scan Angle (Degrees)		Scan Angle (Degrees)	
	0	+50	0	+50
-2.5	149	133	153	137
0	185	183	186	180
+2.5	152	138	151	131

These results at 47°F (worst case) indicated that both bars exceed system level requirements; therefore, they were considered acceptable. Both optical bars met the longitudinal color performance requirements, at all measured wavelengths.

#### 1.3.2 Resolution

Both cameras fully meet the tri-bar resolution performance requirements. (See Table 1-3, summary of the resolution values and acceptance criteria at all three temperatures). The focus position for each camera, for all three temperatures in Chamber A vacuum acceptance tests, is

FWD Camera      42 microns  
AFT Camera      66 microns

~~TOP SECRET~~

~~TOP SECRET~~

TE 0515

TABLE 1-3

SUMMARY OF TRI-BAR RESOLUTION S/N 015  
 (AVERAGE GEOMETRIC MEAN OF FLIGHT AND SCAN IN CYC/MM  
 VACUUM,  $V_x/h = 0.052$ , CONT. ILLUM., IMC DISABLED)

Camera				FWD			AFT		
Temperature				70°	47°	93°	70°	47°	93°
Scan Angle	Field Position	Acceptance Criteria		* 42μ	42μ	42μ	66μ	66μ	66μ
		70°	47° & 93°

Nadir	0°	150	150	183	207	159	185	198	168
55°	2.0°	130	110	174	188	166	157	169	142

\* Average of three readers

### 1.3.3 Film Synchronization

The sync-flash evaluation resulting from three temperature vacuum acceptance tests is presented in tabular form in Paragraph 3.5.1 with out-of-specification values noted. The following paragraphs summarize the analysis of these out-of-specification conditions.

#### 1.3.3.1 FWD Camera, Cross-Track Mean

The nadir position for  $V_x/h = 0.052$  at 93°F indicates a mean WOG (without gravity) value of 0.054 inches per second versus a specification of 0.050. Although this value is only slightly out-of-specification, it is supported by EM Performance Data. A hump in the FBS signal occurred in the vicinity of the nadir collimator such that the sync value increased beyond the specification (See PM-1470X, "Investigation of FBS Disturbance (Hump Anomaly)" dated 6 August 1973); a waiver has been issued as part of the S/N 015 Technical Certification.

~~TOP SECRET~~

~~TOP SECRET~~

TE 0515

#### 1.3.3.2 AFT Camera, In-Track Two Sigma ( $2\sigma$ )

The nadir and  $45^\circ$  collimator positions for  $V_x/h = 0.036$  at  $70^\circ\text{F}$  indicates  $2\sigma$  in-track values of 0.042 and 0.052 ips respectively versus a specification of 0.037 ips maximum. Analysis of EM performance data does not support the photographic results; a waiver has been issued as part of the S/N 015 Technical Certification.

#### 1.3.4 Dynamic Focus

The dynamic focus results of the  $70^\circ\text{F}$  tests at  $V_x/h = 0.052$  and  $0.036$  and the other individual test conditions at  $47^\circ\text{F}$  at  $V_x/h$  of  $0.052$  and  $93^\circ\text{F}$  at  $V_x/h$  of  $0.052$ , show both cameras to be well within 4.9 microns ( $2\sigma$ ).

#### 1.3.5 Midsection, Film Markings

No significant anomalous film markings occurred during acceptance testing. Spurious or misplaced SOF marks were nonexistent.

#### 1.3.6 Electromechanical Performance

The analysis of all acceptance EM data for this model indicates that all EM data requirements were met. A detailed discussion of the EM performance is contained in Section 4 of this report.

TE 0515

## SECTION 2

## SIGNIFICANT ANOMALIES

## 2.1 MALFUNCTION REPORTS

The anomalies discussed in this section have been deemed significant because they impacted performance, or because they caused a configuration modification during the test flow. The complete tabulation of Malfunction Reports (MRs) against S/N 015 has been provided as an integral part of the Technical Certification package. There are no outstanding MRs against S/N 015 as it completed acceptance.

## 2.2 MR 5447 - AFT SIDE FRAME ARTICULATOR TORSION ROD SUPPORT BRACKET TCA VIBRATION FAILURE

Acceptance level vibration testing of the Two Camera Assembly (TCA) induced fractures in two places on the AFT camera torsion rod support bracket (621-3216).

Subsequent investigation of this malfunction report indicated that the sinusoidal vibration exposure spectrum for this TCA had started at 200 Hz and swept down to 5 Hz. This differed from all previous models tested where the spectrum started at 5 Hz and swept up to 200 Hz. It was observed that component brackets swept from low to high frequencies started to exhibit minute (0 - 1/8-inch) cracks only after repeated vibration cycles. Brackets swept from high to low frequencies, however, fractured completely on the first sweep.

A minute crack in this bracket at a resonant point causes the resonant frequency to shift lower, so that as the acceptance vibration frequency sweeps downward it tends to follow the resonance shift, thus aggravating the minute fracture and causing a complete rupture. When the vibration is swept in the opposite direction, the resonance shift is opposite to the direction of vi-

~~TOP SECRET~~

~~TOP SECRET~~

TE 0515

bration application and thus there is no continued vibration at the shifted resonance point. Subsequent analysis and test has also shown that the acceptance vibration envelope is more severe than the vehicles see on an average.

The bracket design has been modified to correct this marginal condition, and a bracket built to the modified design has been successfully tested for structural integrity. Brackets of the modified design have been installed on both sides of S/N 015, and this MR has thus been closed.

### 2.3 MR 5457 - ABNORMAL PLATEN (PL) OPERATION

This MR was prepared on May 6, 1974 during pre-acceptance in-air testing. The AFT platen operated erratically as evidenced by the breakup of the Photo Mode Error (PME), Recycle Mode Error (RME) and PL Tach electromechanical signals. A resultant detailed data evaluation program indicated the anomaly was related to platen operation only.

The film drives and platen were removed from the midsection, and the platen was submitted to a thorough visual examination. No indications of mechanical interference were detected. The next phase of the MR investigation addressed itself to the possibility that some type of electrical transient had precipitated the anomalous performance.

The platen servo electronic box (2A1) was replaced with another 2A1 box with an inherently higher noise threshold. No difference in performance was noted; the anomaly still existed, indicating that the source of the problem was probably external to the 2A1 box.

The investigation subsequently focused on the possibility of excessive noise pickup in the cables that interface with the 2A1 unit, causing erratic platen behavior. The results of this testing indicated that the shielding configuration on the cable leading to the platen motor had a direct effect on platen performance, specifically, (1) when either end of the shield on the motor cable was disconnected, the platen would malfunction in the same mode as the original malfunction and (2) separating the motor and encoder cables by at least four inches decreased the noise on the platen servo 0° marker line (a

~~TOP SECRET~~

~~TOP SECRET~~

TE 0515

counter reset signal) by approximately 55 percent. The shield terminations were reconnected and a new cable routing scheme was implemented to provide more separation between the motor and encoder cables.

Over 5,000 platen operations have been run since the motor and encoder cables were disconnected, examined and reconnected. No repetition of this anomaly has occurred.

In conclusion it is felt that this anomaly was caused by a faulty shield connection in the 2A1 motor cable. This MR has been closed.

#### 2.4 MR 5477 - FILM BREAKAGE, FWD AND AFT CAMERAS

This MR was written on June 18, 1974 at the end of a series of special Chamber A tests. Data review indicated that a system constraint was violated, namely that when running at constant velocity (cv) the system must be brought below camera power off before subsequently recommending film transports on. The following coarse path command sequence occurred as a result: the velocity command ramped to maximum reverse, then ramped to maximum forward, then stepped immediately to maximum reverse, followed by a film break on both cameras in the supply compartment.

As a result of the failure, the system was disassembled and all major sub-assemblies were inspected for damage and reworked as required. Film was found broken on both sides in the SU. Static and dynamic SU brake torque tests indicated a slightly out-of-specification condition on the high limit. Brakes were readjusted.

In the FEV, the AFT side tensioner roller was found out of alignment. Several rollers on both FWD and AFT sides failed roller rundown tests and were either replaced or had preload adjusted.

Material from both stacks was retrieved, pieced together, and processed. On the FWD side, the film had been broken in four places in the SU. In addition, 26 inches had been pulled through a closed seal door; required force was 20 to 22 pounds.

2-3

BIF 007-10003-75A

~~TOP SECRET~~

~~TOP SECRET~~

TE 0515

On the AFT side, the film was broken in two places. In addition, 43 inches had been pulled through a closed seal door; required force was also 20 to 22 pounds.

Analysis determined the tension in the film on the SU side of the seal door (both sides) reached about 74 pounds. In the TCA, it probably reached 54 pounds. Based on reasonable air bar coefficient of friction values, the tension in the PL area was calculated at about 20 to 22 pounds.

All rollers on the FWD and AFT sides were checked for preload, runout, and rundown. Seventeen rollers required adjustment and 12 rollers were replaced. Alignments in critical areas were checked and adjusted as required.

Test flow was resumed successfully.

#### 2.5 MR 5494 - 100 Hz OSCILLATION OUTPUT FILM DRIVE SUMMED ERROR

This MR was prepared as a result of a complete review of the electromechanical signals on July 30, 1974 prior to Chamber A in-air testing. This data review is standard practice.

The FWD camera output film drive summed error exhibited an abnormal 600 millivolt peak-to-peak oscillation at 90 to 103 Hz. The output film drive servo box (3A1) was replaced with another unit and the anomaly disappeared. The new unit (S/N 1032) was retained for all subsequent testing, and will stay with this model. The suspect 3A1 box (S/N 1022) was subsequently installed and tested on the AFT side of S/N 015, on the validation model, on both sides of S/N 016, and on the AFT side of S/N 017. In every case, operation was nominal. The anomaly did repeat when the S/N 1022 box was reinstalled on the FWD side of S/N 015. The unit was returned to the vendor for investigation, and no anomalous condition was found. The acceptance test was rerun and the box passed. The box has been added to the suspect box list and will continue to be monitored on the AFT side of S/N 017.

~~TOP SECRET~~

~~TOP SECRET~~

TE 0515

## 2.6 MR 5485 PNEUMATIC TUBING KINK

This MR was written as a result of an emergency shutdown (ESD) that occurred on the FWD side during a creep run. Investigation found a severely kinked urethane tube that supplies nitrogen to the Crossover Air Bar. The kink in the tubing cut off the nitrogen to the air bar causing high drag on the film. The ESD resulted subsequently when the looper drifted into its stop. A tube with an internal spring has been substituted along with a length callout to correct this situation.

TE 0515

## SECTION 3

## PHOTO-OPTICAL PERFORMANCE

## 3.1 OPTICAL BARS

3.1.1 Optical Set Identification

The operational cameras for S/N 015 Sensor Subsystem are identified as FWD camera (Optical Bar A) and AFT camera (Optical Bar B). The optical glass sets are identified as 036 for the FWD camera and 043 for the AFT camera. These set nomenclatures (See Table 3-1) serve as camera identifiers for operational purposes and for post flight analysis, etc.

TABLE 3-1

CAMERA IDENTIFICATION

Optical Bar	Flight Direction	Optical Set
A	Forward	036
B	Aft	043

3.1.2 Physical Characteristics

The two physical characteristics (Table 3-2) measured for both cameras are focal length and T number. Note from the tabular values, both cameras are within acceptable design specification requirements.

TABLE 3-2

PHYSICAL CHARACTERISTICS, FWD AND AFT CAMERAS

Characteristic	Specification	FWD Camera	AFT Camera
Focal Length (inches)	60 $\pm 0.2$ (2 $\sigma$ )	59.9704	59.9963
T Number	3.5 maximum	3.46	3.46

~~TOP SECRET~~

~~TOP SECRET~~

TE 0515

### 3.1.3 Longitudinal Color

The on-axis longitudinal color response (Figure 3-1) was plotted for both optical bar sets, and the focus position was measured at six wavelengths: 4720Å, 5175Å, 5500Å, 6050Å, 6630Å, and 6975Å.

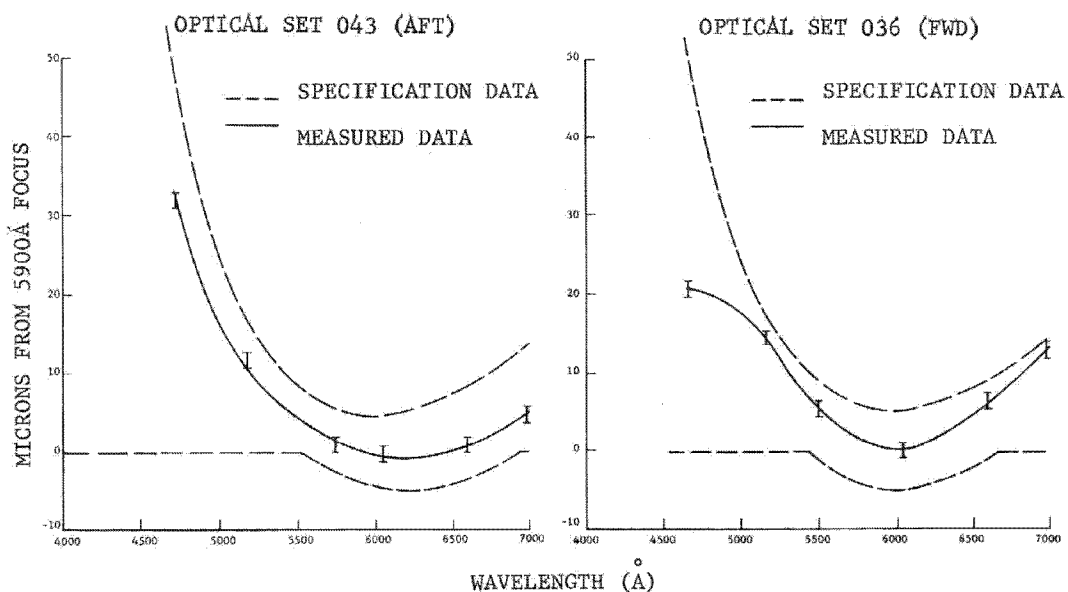

Figure 3-1. On-Axis Longitudinal Color Response

### 3.1.4 Focal Plane Tilt

The field curvature for both optical bar sets was plotted (See Figure 3-2), and as the plots indicate, curvature was determined from monochromatic data taken in Chamber D. Chambers A and A-2 sign conventions were used to facilitate additional plotting of the film plane profile across the slit based upon the resolution data. Also shown are both in-track and cross-track best focus.

~~TOP SECRET~~

~~TOP SECRET~~

TE 0515

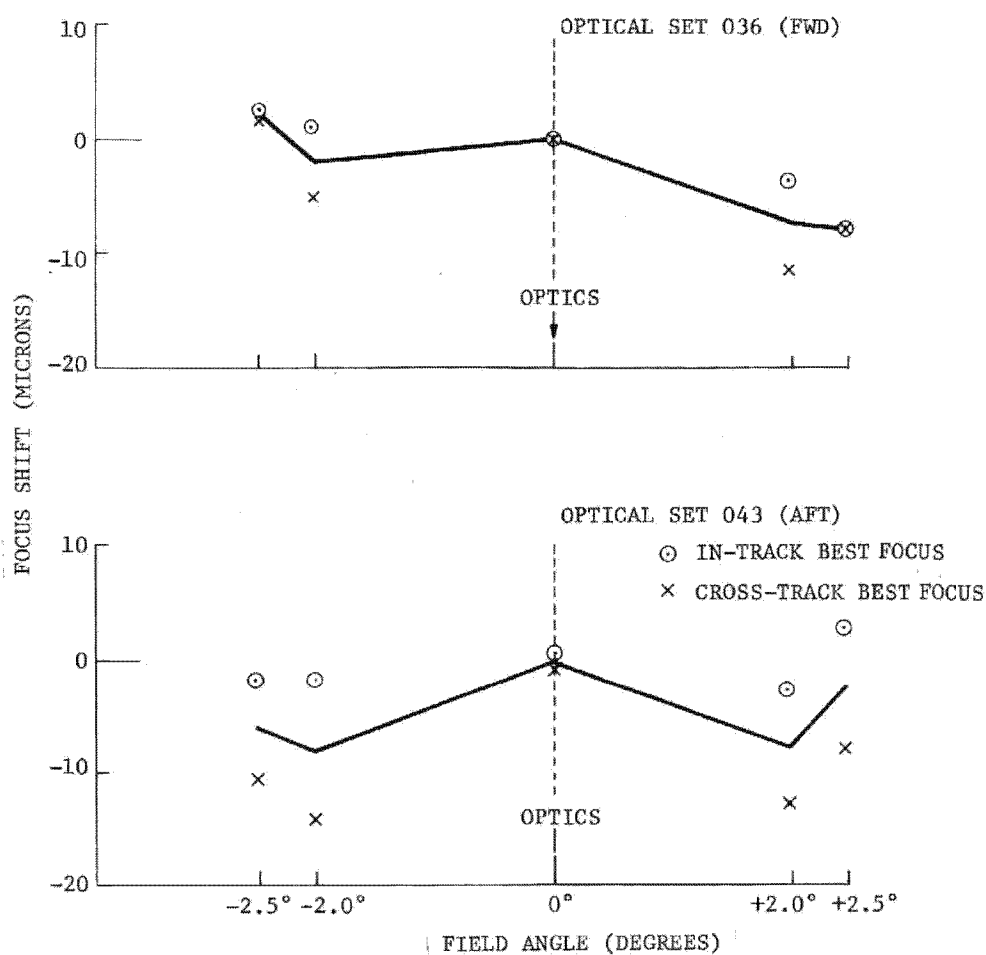

Figure 3-2. Field Curvature, Optical Bar, Glass Sets 036 and 043, FWD and AFT Cameras

This Chamber D data showed:

- Optical Bar Set 036 has a  $9\mu$  tilt ( $4.4\mu$  per  $1/2$  slit) in the advance direction.
- Optical Bar Set 043 has a  $2\mu$  tilt ( $1.2\mu$  per  $1/2$  slit) in the retreat direction.

~~TOP SECRET~~

~~TOP SECRET~~

TE 0515

### 3.1.5 MTF Comparison

Modulation transfer functions (measured at 70°F, 93°F and 47°F) and their respective specification curves for each optical bar were compared as shown in Figures 3-3 through 3-8. The comparisons show the off-axis MTFs at 47°F fall below specification for the FWD optical bar at the  $\pm 2.5^\circ$  fields in both flight and scan direction; these were at various frequencies greater than 132 1/mm for the flight direction and greater than 164 1/mm for the scan direction.

The major cause of the low MTFs was gravity-induced astigmatism in the fold. After accounting for this error, however, the MTFs and predicted resolution are above specification (See Section 6).

For 70°F, the MTF ratios of post-vibration to pre-vibration values at 140 cy/mm indicate optical performance to be essentially unchanged by exposure to acceptance vibration (See Table 3-3).

TABLE 3-3

MTF RATIOS, POST-VIBRATION TO PRE-VIBRATION AT 140 CYC/MM

Field Angle	Optical Bar Set			
	036 (FWD)		043 (AFT)	
	Flight	Scan	Flight	Scan
+2.5°	1.02	1.02	0.93	0.92
0°	1.01	1.02	0.94	0.96
-2.5°	1.00	1.01	0.93	0.95

### 3.1.6 Passive Focus Shift

Both cameras were tested in a Chamber D test environment. Following thermal stabilization at each of the 47°F and 93°F environments, focus change was measured. The amount of defocus at field positions 0° and  $\pm 2.5^\circ$  is related to the focus positions established at 70°F. Focus data (Table 3-4) is essentially a measure of the optic's ability to maintain, passively, the best focus position over the operating thermal range. The signs shown in the table reflect the normal Chamber A sign convention of plus being away from the last optical surface.

TABLE 3-4

PASSIVE FOCUS POSITION DATA

Optical Bar		036 (FWD)	043 (AFT)
Temperature (°F)	Field Position (Degrees)	Defocus (Microns)	Defocus (Microns)
93	2.5	+2.6	+4.5
	0	+0.4	-0.3
	-2.5	+4.5	-1.3
47	2.5	-1.7	+3.0
	0	-1.1	+7.3
	-2.5	-1.2	+6.3

The data (Table 3-4 and Figure 3-9, passive focus error effects on field curvature and tilt) shows the following:

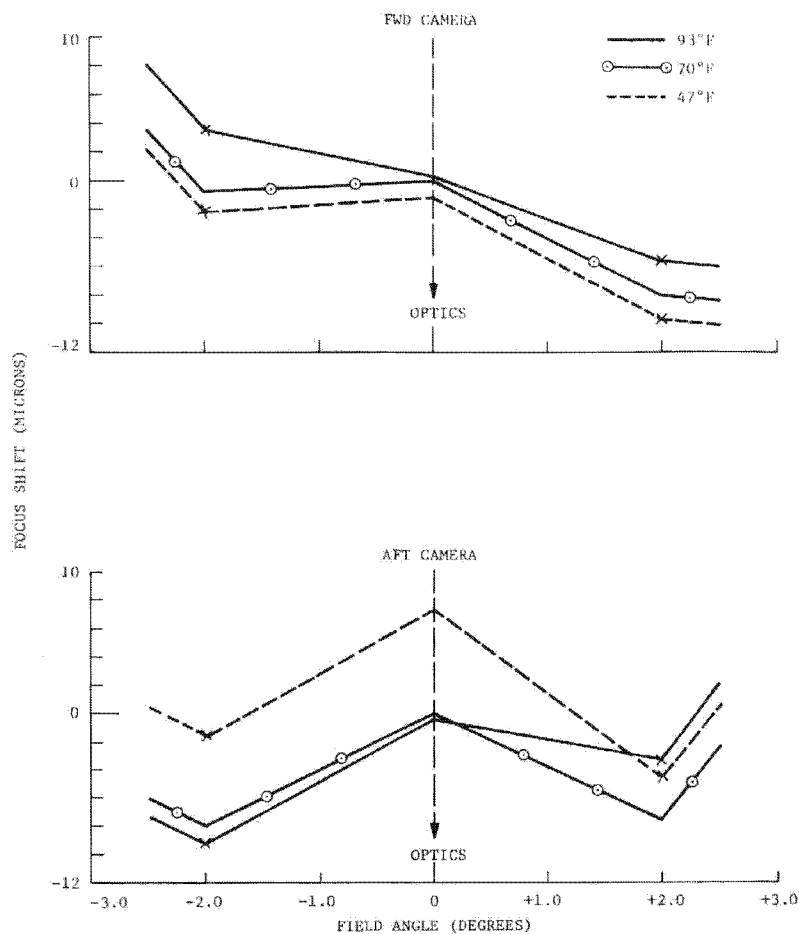

a. The FWD optical bar meets the  $\pm 4.5\mu$  performance requirement at both 93°F and 47°F in all fields.

b. The AFT optical bar does not meet the requirement at 47°F in the 0° and  $-2.5^\circ$  field positions, but does at 93°F in all field positions.

~~TOP SECRET~~

~~TOP SECRET~~

TE 0515

NOTE: Temperature data collected at 0°, +2.0° and +2.5° of field at 70°F only.  
The +2.0° data (X) is extrapolated for 93°F and 47°F.

Figure 3-9. Effect of Temperature on Field Curvature and Tilt, FWD and AFT Cameras

Although optical bar 043 does not meet the  $\pm 4.5\mu$  passive focus control specification, predicted on-orbit performance of this optical bar was well above specification at all temperatures. This prediction assumed the worst-case condition -- focus would not be actively controlled based on known temperatures. As a result of predicted performance, this optical bar was moved ahead in assembly.

~~TOP SECRET~~

~~TOP SECRET~~

TE 0515

### 3.1.7 Gravity Induced Defocus and Aberration

Testing in a gravity field causes errors in focus and wavefront aberration that should be accounted for. The measured gravity induced defocus and astigmatism for this system are as follows:

<u>At Nadir</u>	<u>FWD Camera</u>	<u>AFT Camera</u>
Gravity induced defocus	7.1 $\mu$	8.1 $\mu$
Gravity induced 0° - astigmatism	-0.08 $\lambda$	-0.14 $\lambda$
<u>Chamber D Correction</u>		
Gravity induced 45° - astigmatism	0.08 $\lambda$	0.08 $\lambda$
Plus defocus is away from the optics.		

### 3.1.8 Dynamic Gravity Corrections

Dynamic gravity corrections (Table 3-5) for both optical bars are used to adjust the measured image motion values for both chambers (A and A-2).

## 3.2 MIDSECTION RESOLUTION PERFORMANCE

### 3.2.1 Thru-Focus Resolution

#### 3.2.1.1 Acceptance Data

The resolution acceptance criteria, specified in Paragraph 3.1.1 of S/N 015 CEI specification and listed in Table 3-6 herein are to be met at a  $V_x/h$  of 0.052 rad/sec at a single selected plane of best focus in the 120° scan mode. Raw data is obtained by reading tri-bar resolution targets recovered from CEI runs 101, 111 and 115 (70°F, 47°F and 93°F, respectively). This raw data is read in both the in-track and cross-track directions, and the geometric mean is calculated for each frame. These geometric means are then arithmetically averaged for the total number of frames at each focus setting for each collimator position. The in-track and cross-track points of best focus are selected by a computer program that evaluates the output of automicrodensitometer scanning of the line targets. The arithmetic average of these points establishes the point of best focus for each collimator position (see Figures 3-10 through 3-15, raw in-track, cross-track, and geometric mean data).

55°	2.0°	130	110	174	188	166	157	169	142

\* Average of Three Readers

A point of best focus of 42μ for the FWD camera and 66μ for the AFT camera was selected to give best performance across the three collimator positions at all temperatures for S/N 015. The raw data resolution values at these positions are tabulated in Table 3-6. All values exceed their corresponding specification criteria.

## 3.2.1.2 Acceptance Data Analysis

Realistic system operational performance evaluation is based upon the analysis of corrected acceptance resolution data. Modifying raw resolution data for collimator defocus, gravity and film flatness characteristics results in the corrected data.

TE 0515

Collimator defocus corrections account for any deviation of the target reticle from the true infinity focus position. These deviations are determined interferometrically via the reticle corner cubes; Tables 3-7 and 3-8 tabulate these magnitudes. The correction factor for gravity compensates for its varying effect on the optical elements at different orientations as the bar rotates. The values tabulated in Tables 3-7 and 3-8 reflect the average measured values from a series of tests on several optical bars in Chamber C.

Film flatness effects are determined by a series of measurements made on selected segments of film used during the CEI through-focus runs; these film samples are cut out prior to processing and tested on the abbreviated film path (AFP). Traces are made across the film web with a photonic sensor having measurement repeatability of one micron. Also tabulated in Tables 3-7 and 3-8 are these film flatness corrections.

Applying these tabulated correction factors to the in-track and cross-track raw acceptance data brings about a shift in focus position of the curves; and because the magnitudes of the in-track and cross-track focus corrections are different, the resultant mean curves shift in focus as well as resolution value. In Figures 3-16 and 3-17 are corrected in-track, cross-track and geometric mean resolution data for S/N 015 at 70°F. A corrected point of best focus of 36 $\mu$  for the FWD camera and 54 $\mu$  for the AFT camera results in the corrected resolution values listed in Table 3-9. These corrected values now represent a measure of system operational performance. Note that these focus positions are chosen to give best performance across the field at infinity focus; they are not intended to reflect the final flight focus settings.

#### 3.2.1.3 Resolution Performance at $V_x/h = 0.036$

Resolution performance determination at a  $V_x/h$  of 0.036 is categorized in the CEI specification as an essential test for information; acceptance criteria do not apply. In Table 3-10, the resolution data for CEI run 103 is tabulated. Note from the table that a re-read of the FWD camera data revealed grossly different results; reader variability is a problem (see Paragraph 3.2.1.4).

Comparing aft camera performance and reread forward camera performance with their associated mean acceptance data (CEI 101) indicates excellent repeatability. Through-focus plots of this geometric mean performance for CEI 103 are shown in Figure 3-18.

#### 3.2.1.4 Reader Variability

CEI Run 101 for both the FWD and AFT cameras, as well as CEI Run 103 FWD camera were reread at AFSPPF by the same personnel in response to Customer direction. The results of CEI 103 FWD camera reread were shown in Table 3-10; the results of CEI 101 reread are shown in Table 3-11 in comparison form. Reviewing Table 3-11 shows a significant problem -- a wide range of reader variability -- when attempting to evaluate system performance.

### 3.2.2 Performance at 0.6-Inch Slit Width

CEI Runs 109 (0.3-inch slit width) and 110 (0.6-inch slit width) are dual gamma runs for information; acceptance criteria do not apply. A meaningful analysis of these runs (see Tables 3-12 and 3-13) would be:

a. to compare CEI Run 109 with CEI Run 101 to evaluate differences in dual gamma processing.

b. to use the measured smear performance from CEI 109 and 110 (three count and seven pulse count, respectively), predict the 0.6-inch slit width resolution performance and compare this prediction with the actual measured resolution data.

Comparing tri-bar resolution values for CEI 101 and 109 for FWD and AFT cameras shows both 0.3-inch slit width runs exhibit essentially equivalent performance. Reviewing predicted 0.6-inch slit width performance versus actual shows good agreement on the FWD camera. However, the AFT camera comparison shows the 0.6-inch slit width measured performance to be much higher than predicted, and as a point of interest higher than the 0.3-inch slit width data in most cases.

The AFT camera differences are attributed either to reader variability or to the fact that measured smear performance tabulated does not completely describe the image motion characteristics.

### 3.2.3 Color Performance, S0-255

Tri-bar resolution for S/N 015 with S0-255 color film (see Table 3-14) is typical of resolution experienced in previous systems. Also typical of previous systems are the through-focus plots of Figure 3-19 indicating an approximate focus shift of 30 microns from 1414 black and white film focus position.

### 3.2.4 In-Flight Changeable Filter Performance

The interchangeable filter (filter/flop) test for CEI 102 was conducted to confirm tri-bar resolution and focus performance as the Wratten 12 and 2E3 filters are interchanged in the optical path. The interchange was made three

times at the best focus position for each camera (see Table 3-15); focus variations were found by evaluating the line focus targets (see Table 3-16). Resolution performance is equivalent for both cameras within the reader variability; and reviewing the data shows excellent focus repeatability.

### 3.2.5 Low Voltage Verification

The low voltage verification test (CEI Run 108) is performed to evaluate resolution performance when the primary vehicle power source voltage is at the lowest allowable level. Performance degradation is measured by comparing the CEI Run 108 performance with CEI Run 101, an equivalent run at nominal primary voltage. The results (see Table 3-17) indicate no significant performance degradation when the primary voltage is low.

### 3.2.6 Operational Mode Verification

Operational mode verification tests are designed to measure the resolution performance at scan angles and centers other than 120° and zero center. The CEI specification states that this data is to be provided for information only, but that as a goal, the acceptance requirements apply.

Note from the measured resolution performance of the operational mode tests tabulated in Tables 3-18 and 3-19 that all values were obtained at the same platen position as the acceptance data. The data shows results only for those collimator positions where a complete target is available. Reviewing

	108		185	135	158	206	159	181	187	127	154

the data shows the goal of acceptance resolution values has been exceeded at every position by at least 34 cycles/mm for the FWD camera and 22 cycles/mm for the AFT camera. Generally the performance of both cameras at the scan angles and centers shown is equivalent to the acceptance resolution performance indicated at a 120° scan angle.

### 3.3 MIDSECTION DYNAMIC FOCUS

The mean and two sigma values at each of the three test temperatures (see Tables 3-20 and 3-21) were obtained by reading raw line target data, from CEI Runs 101, 103, 111 and 115. The measured two sigma values, in particular, are all well controlled, the greatest value being 3.2 microns. The average of the in-track and cross-track two-sigma values at each temperature is shown in the tables in parentheses. These values meet the dynamic focus criteria of a value no greater than  $\pm 4.9$  microns (2σ) for each individual test condition, as specified in Engineering Change Proposal No. 11302 (approved 27 April 1974).

The dynamic focus results for all test temperatures combined at  $V_x/h = 0.052$  in Table 3-22 show the average of the in-track and cross-track two-sigma values for the FWD camera (7.35μ) is over the specification limit of 6.5μ. ECP No. 11302 has eliminated this method of calculation for all systems beyond S/N 015.

TE 0515

Dynamic focus test results at 70°F for the two operational speeds of  $V_x/h = 0.052$  and  $0.036$  shown in Table 3-23 demonstrate that both cameras fully meet CEI specification requirements of  $4.9\mu$  average  $2\sigma$ .

### 3.4 MIDSECTION FOCAL PLANE TILT AND FIELD CURVATURE

#### 3.4.1 Focal Plane Tilt

Platen tilt determination plots compare Chamber "A" line target focus data with Chamber "D" focus data that has been adjusted for zero tilt and normalized at nadir for 70°F. The tilt plots of raw CEI data for all three test temperatures are shown in Figure 3-20, and the required tilt corrections calculated from the raw line target data for all Chamber "A" vacuum tests are summarized in Table 3-24. The correction factors for gravity, collimator defocus, and film flatness (See Paragraph 3.2.1.2) have been applied to this raw data; the results are also summarized in Table 3-24. A ten micron mechanical tilt was incorporated in the FWD camera platen based on Chamber D data. Since no electrical tilt corrections have been made in either camera, a  $\pm 20$  micron electrical tilt capability remains.

#### 3.4.2 Apparent Field Curvature

The values shown in Table 3-25, summary of raw field curvature data, are typical of previous systems. A meaningful data evaluation would be to reduce Chamber "A" raw data to optical performance and compare these results to Chamber "D" data.

The effects of gravity, collimator defocus, and film flatness are shown in Paragraph 3.2.1.2; the magnitude of each correction factor relative to field angle is shown in Tables 3-7 and 3-8. In addition, recent tests performed on the Engineering Model have indicated a dynamic film profile exists during recycle at  $120^\circ$  scan. This scan angle to field angle relationship is shown in Figure 3-21 with tabulated magnitudes.

Figures 3-22 and 3-23 present the field curvature evaluation for CEI 101 with the corrections reducing raw Chamber "A" data to optical performance applied incrementally. Table 3-26 summarizes the evaluation of optical field curvature performance in Chamber A for all vacuum runs.

### 3.5 FILM SYNCHRONIZATION

#### 3.5.1 Acceptance Data

The acceptance data requirements for sync flash measurements apply to type 1414 film at Vx/h values of 0.052, 0.044 and 0.036 at a temperature of 70°F (Tables 3-27 through 3-29). Acceptance requirements at 47°F and 93°F apply at a Vx/h value of 0.052 only. The appropriate mean and two sigma CEI specification limits are shown at the tops of Tables 3-27 through 3-29.

As mentioned in Section 1, the out-of-specification data points are:

<u>Camera</u>	<u>Vx/h</u>	<u>Value</u>	<u>Amount Out of Spec</u>
FWD (A)	0.052	CT/0° - Mean @ 93°F	0.004 ips
AFT (B)	0.036	IT/0° - 2σ @ 70°F	0.005 ips
AFT (B)	0.036	IT/45° - 2σ @ 70°F	0.015 ips

The FWD camera anomaly, which occurred at 93°F, was caused by a film-to-bar synchronization (FBS) "hump"; this hump occurred during the time that the "C" targets were flashed on the nadir collimator in Chamber A. (The phenomenon of "humps" was investigated in detail; the results were presented in PM-1470-X.)

In summary, these FBS humps are caused by transient voltage inputs to the metering capstan servo from the MC/OB phase lock loop. These transients are caused by non-linearities in the phase detector output that occur when the position error passes through zero. This condition, however, does not reflect any hardware failure or degradation; it represents a predictable occurrence of a normal system.

The AFT camera in-track two-sigma out-of-specification values at Vx/h of 0.036 are not supported by an evaluation of electromechanical data. There is no indication of a hardware malfunction causing this anomaly, and, therefore, no corrective action has been taken. A waiver has been issued as part of the technical certification.

### 3.5.2 Operational Mode Verification, Synchronization

These operational mode verification tests (CEI Runs 119 through 129) are run as essential tests for information. The CEI specification states that the smear velocity errors calculated from the test results shall be provided with the acceptance data for information only.

The tests are conducted with the Servo Inhibit Assembly (SIA) enabled. Tables 3-30 and 3-31 provide the data required by the CEI specification. The acceptance criteria shown in Tables 3-27 through 3-29 are to be used as a design goal for these tests. A review of the gravity-corrected mean data shows that all values on both cameras, and all  $2\sigma$  values, with one exception (0.007 ips out of design goal), meet the design goal requirements.

### 3.5.3 On-Orbit Adjust Assembly (OOAA) Calibration

The On-Orbit Adjust Assembly calibration data provided herein is required as an essential test for information by the CEI specification. The specific CEI wording is: "the OOAA shall be verified on each camera in both the in-track and cross-track directions at OOAA settings as described in test numbers 105, 106 and 107". The calibration curves reflecting the test data for these runs are presented in Figures 3-24 and 3-25.

### 3.5.4 SO-255 Performance, Synchronization

The synchronization performance of color film (SO-255) is measured during Chamber A testing. The test film was measured at WAFB and the results are presented in Table 3-32. No CEI performance requirement exists for color film; however, the performance measured is typical of color performance on previous models.

## 3.6 FILM MARKINGS

Film markings such as static discharge marks and fog marks either appear light, occur infrequently, or are confined to areas outside of the photographic format. Overall light, intermittent emulsion scratches are found

throughout all testing; this situation reflects normal performance as noted on all previous systems. And, no misplaced or spurious start-of-operations or start of frame marks were noted during both format tests and 70°F vacuum acceptance tests.

### 3.7 FORMAT TESTING

All photographic format measurements comply with the format drawing tolerances and CEI specification requirements.

### 3.8 MIDSECTION ASSEMBLY, PITCH TEST

The purpose of the pitch test, conducted during Chamber A testing of S/N 015, was to continue the investigation into the causes of the apparent field curvature as measured in Chamber A. Data correlation is also achieved by repeating the test in Chamber A-2. The test matrix was similar to that used in Chamber A-2 testing. A through-focus run of 20 frames at each of the focus positions was made at each of the following field positions,  $\pm 2.5^\circ$ ,  $\pm 2.0^\circ$ ,  $\pm 1.0^\circ$  and  $0^\circ$  using a  $30^\circ$  scan angle length at a  $0^\circ$  scan center.

The Westover readings of the peak geometric mean tri-bar resolution at each pitch and consequent field angle are summarized in Table 3-33. The geometric mean through-focus plots for each pitch angle are shown in Figure 3-26.

The field curvature evaluation technique used in Paragraph 3.4.2 can be applied to evaluate the pitch test data. The data must be corrected for collimator and gravity effects; in addition, the data must be corrected for four microns of tilt due to primary mirror decentration and four microns due to a change in mirror deformation and metering rod compression that results from variations in pitch angle. The material corrections consist of both film flatness characteristics and material dynamic effects. The latter stems from the recent series of testing on the Engineering Model; these tests indicated that a dynamic film profile exists during recycle at 052/30°/0°. This scan angle to field angle relationship is shown in Figure 3-27 with tabulated magnitudes. Table 3-34 shows all of the required corrections to reduce pitch test line data to optical performance.

at the operating feed pressure of 106 psia. Figures 3-1 and 3-2 are a history of calculated thrust values for RCS-1 and RCS-2 through Rev 2862. Thrusts are calculated from thrust chamber instrumentation, except the REA-4 thrust which was calculated from attitude gyro response after Rev 1352. The dashed lines (called the repeatability bands) on Figures 3-1 and 3-2 represent the expected variations (based on ground tests) in the undegraded steady state thrust levels at the flight feed pressures.

Although it was later determined that thrust levels would have been adequate for all maneuvers, startup thermal effects and pulse shape distortion on the high duty cycle pitch thrusters (REA 3 and REA 7) led to the conservative option of switching to RCS-2 thrusters for RV-3, RV-4, and deboost. Similar startup transients and pulse shape distortion had preceded thermal choking in ground tests under heat soak-back conditions which can occur during the RV hold period. The solo pitch and hold test on Rev 2862 did not show the thermal choking that was experienced in ground test even though more pulses had been accumulated and the feed pressure was lower. It is theorized that the higher feed pressures, the lower propellant temperature, and the lower duty cycle during the SV-13 flight delayed the onset of thermal choking. It is also noted that considerable differences between thrusters were experienced in the ground testing.

REA 3 stayed within the repeatability bands throughout the flight. REA 7 is estimated to have fallen out of the repeatability bands at about 139 days which exceeded the minimum prediction of 120 days. REA 7 then lost thrust more slowly than would be expected from Block I and Block II experience. REA 3 can be considered to have exceeded and REA 7 to have equalled the performance expected from ground test results for high duty cycle thrusters. Four of the low duty cycle thrusters (REAs 2, 1, 4, and 8) fell out of the repeatability bands between 100 and 140 days, whereas they had been expected to stay within the bands for a minimum of 160 days. Like the high duty cycle REAs, the thrust decay was slow and the thrust level did not fall below the minimum required for control during the flight. The lifetimes of the low duty cycle thrusters were estimated based on the ground tests of only four thrusters; confidence in the estimated lifetimes will increase as flight experience is accumulated.

Estimated total pulse counts for both RCS-1 and RCS-2 thrusters are shown in Table 3-2.

reverse for deboost on Rev 2200. RCS-1 and RCS-2 thrust is calculated by thrust chamber instrumentation and compared to the expected steady state thrust level without degradation at flight feed pressure plus or minus thruster-to-thruster and run-to-run repeatability.

Although thrust levels were adequate for all maneuvers, repeated spiking above feed pressure observed during high activity maneuvers on REA 6 and REA 7 led to the conservative option of switching to RCS-2 thrusters for RV-3, RV-4, RV-5, pitch down maneuvers and deboost. Since thrust chamber pressure is not observed by telemetry during payload operations, spiking trends cannot be established for payload activity. Single bar mono operation causes high thruster activity with long pulses and high thruster temperatures, conditions which cause maximum thrust chamber spiking. Concern for vehicle safety and potential thruster leakage from reverse propellant flow through the thruster valve during the single bar payload operation prompted switching to RCS-2 thrusters for attitude control on Rev 2726 until the completion of the mission. It should be noted that normal two-bar mono and stereo use only minimum impulse bit pulses which do not cause spiking. Observed spike magnitudes during non-payload maneuvers reached a maximum 173 psia during the mapping camera calibration maneuvers on Rev 1659 which is far below the Reaction Engine Module (REM) structural limit of 650 psia. However, low feed pressure operation from the revised propellant management requirements resulted in spike energies above feed pressure ( $0.50 \text{ lb-sec/in.}^2$ ) greater than SV-13 ( $0.15 \text{ lb-sec/in.}^2$ ) or ground test experience ( $0.20 \text{ lb-sec/in.}^2$ ). No thruster valve leakage from reverse flow was experienced even though SV-13 and ground test experience was exceeded.

All pitch/roll thrusters (REA 2, REA 3, REA 6 and REA 7) and two yaw thrusters (REA 1 and REA 8) performed close to the upper limit thrust decay prediction which was established based on SV-13 and ground test experience. Yaw REA-4 performed between the average and lower limit thrust decay prediction and yaw REA-5 was

than predicted. REA 1 fell out of the acceptability band at approximately 120 days, REA 4 at 130 days and REA 3 at 150 days, but as expected from SV-13 experience, thrust decay slopes were gradual. The thermal choking experienced on REA 7 during the Rev 2889 solo RV simulation is within predicted thermal margin limits based on number of pulses, duty cycle, propellant temperature and feed pressure.

Results of SV-14 thruster performance are being factored into thruster life prediction models.

Estimated total pulse counts for both RCS-1 and RCS-2 thrusters are shown in Table 3-2 and indicate relative activity of the thrusters.

3-2

~~Top Secret HEXAGON~~

## 3.3.4 RCS-1 Thrust Chamber Pressure Output Anomaly

Beginning with thruster firings for orbit adjust 30 on Rev 1352, the thrust chamber pressure transducer (B004) for yaw thruster REA-4 indicated no output. The REA 4 nozzle temperature (B054) and a comparison of REA 4 and REA 5 valve driver activity to the yaw gyro rate data showed that REA 4 thrust output was normal. Switchover from PCM 1/Remote A to PCM 2/Remote B showed that the anomaly was due to lack of signal output from the REM pressure transducer. An output reading was observed on B004 for two seconds during RV-5 (Rev 1825) indicating an intermittent condition in the transducer electrical circuit.

The most probable cause of the output loss was an open pressure transducer input power circuit. Pressure transducer ground testing uncovered a weakness in the input power EMI suppression inductor (MS90537-57) where temperature cycling caused broken wires and welds inside the inductor. Beginning with SV-14, a higher reliability version of the inductor (M39010) has been incorporated in the pressure transducer design. Vendor testing at both the pressure transducer assembly and inductor piece part level has confirmed improved reliability under temperature cycling conditions.

were positioned at +18° for the remainder of the active mission. The solar array deployment mechanism has been modified for Block III and the similar deployment histories of the two arrays correlated closely with ground test results thereby indicating that the objective of eliminating the uncontrolled friction has been achieved.

The solar array output varied from 24.0 ampere-hours/rev to 24.4 ampere-hours/rev throughout the flight exceeding the specification value. Degradation of the solar arrays was less than 3% in the first 30 days and less than 1% during the remainder of the mission.

### 3.6.2 Main Bus Voltage

The main bus voltage varied from a low of 26.5 volts during payload operations with a bus load of 66.0 amperes to a high of 31.4 volts in solo operations during the K-2 bypass relay close test.

### 3.6.3 Power Capability and Usage

In the beginning of the mission, power usage exceeded the total power generated by the solar arrays. Adequate power was available to support all primary payload operations. Power management during this period consisted of alternating and reducing the operations of the life-boat tank heaters, NAVPAC, MESA, the nickel-hydrogen battery experiment,

By Rev 1477 (with an improved beta angle and lower loads through the recovery of RV-1 and RV-2), sufficient power was available for all.

During the primary mission the power usage ranged from an average of 23.9 ampere-hours/rev during the first 15 days to 20.4 ampere-hours/rev during segment 4. The maximum period without a K-2 was 81 revs (Rev 184 to Rev 265). During this period the minimum system state-of-charge was 182.4 ampere-hours (76%).

### 3.6.4 Type 40 Battery Performance

Battery performance was excellent throughout the flight. As observed in the sunrise ES record data, the four battery voltages did not vary by more than 0.2 volts. Maximum sunrise load share variation observed was 0.4 amperes. After thermal stabilization, the battery temperatures cycled between 44°F and 49°F.

~~Top Secret~~

### 3.4 ORBIT ADJUST SYSTEM (OAS)

The orbit adjust system was operated 60 times during the active mission and four times during solo operations. Following the deboost, a propellant depletion firing was accomplished. The average propellant usage was 19.1 pounds/day during the active mission. The total propellant consumption (including deboost) was 3607 pounds. OA burns occurred every three days and the orbit parameters were such that only two negative firings were needed to control the argument of perigee.

The catalyst bed pressure drop factor (K-factor) began its decline earlier than on previous flights and stabilized at a value of approximately 16 instead of the previous range of 18 to 22. Engine performance, however, was normal throughout the mission.

### 3.5 LIFEBOAT SYSTEM

The lifeboat system was enabled for a health check on Rev 18 and for each RV separation. Performance of the magnetometers and gyros was normal, and no anomalies were noted.

### 3.6 ELECTRICAL DISTRIBUTION AND POWER (EDAP)

The Block III solar array deployment mechanism has been modified but operationally remains the same. There were four type 40 batteries: three for the main bus and one for the lifeboat bus. A commandable K-2 bypass relay was added to each charging circuit to provide a redundant capability in the event of a K-2 relay malfunction such as the one that occurred on SV-12. The lifeboat battery could also be connected to the main bus and an automatic disconnect triggered by a high main bus current or a low lifeboat battery state of charge was included to protect the lifeboat battery. Also a gross main bus overcurrent would open an 80 ampere fuse, isolating the lifeboat battery. Modifications were also made to permit the nickel-hydrogen battery experiment to receive that portion of the solar array output that is not used when the K-2 relay is in the open position.

#### 3.6.1 Solar Arrays

The SV beta angle varied from +22° to +10° so, after deployment at the first station pass (Indi), the solar arrays

The Orbit Adjust System (OAS) was operated 63 times during the active mission and for a two segment deboost (followed by a burn-to-depletion firing). Other than deboost and the depletion burn, no negative firings were performed.

The average propellant usage for orbit adjusts was 18 pounds/day for the mission length. The total propellant consumption through the orbit adjust engine (including deboost and depletion burn) was 3446 pounds. ~~A summary of the orbit adjust~~ The catalyst bed pressure drop factor (K-factor) exhibited characteristics quite similar to that observed during the last mission (SV-13). It stabilized at a value of approximately 15 for the later half of the mission, as before, but with a slight decaying trend during the last few OA firings.

OA engine performance, however, was nominal and satisfactory throughout the mission series.

### 3.5 LIFEBOAT SYSTEM

The Lifeboat System was enabled for a health check on Rev 18 and for each RV separation. The magnetometer and gyro performances were normal and no anomalies were noted.

### 3.6 ELECTRICAL DISTRIBUTION AND POWER (EDAP)

The SV-14 configuration, with one major exception, was basically similar to SV-13. The S77-2 experiment was installed on +Y Pallet, replacing the  $\text{NiH}_2$  battery experiment. This resulted in heavier than usual loads, especially in the early stages of the flight.

#### 3.6.1 Solar Arrays

*Insert V* The SV beta angle varied from 18.5 degrees to 22.5 degrees so the solar arrays were positioned at +18 degrees throughout the mission except for solo testing of the position switches.

mission.

### 3.6.2 Main Bus Voltage

The minimum bus voltage during payload operations was 26.8 volts, on Rev 1985, with a bus load of 66.0 amperes. The highest voltage observed was 31.7 volts on Rev 2389 HULA.

### 3.6.3 Power Capability and Usage

The solar array output varied from 25.66 ampere-hours/rev on Rev 7 to 23.42 ampere-hours/rev on Rev 2859 throughout the mission. During the primary mission the power usage ranged from an average of 382 ampere-hours/day during the first 36 days to 360 ampere-hours/day during Segment 4. The maximum period without a K2 was 172 revs (Rev 1884 to Rev 2056). During this period, the minimum system state-of-charge was 158 ampere-hours.

### 3.6.4 Type-40 Battery Performance

Battery performance was excellent throughout the mission. As observed in the sunrise ES record data, the four battery voltages did not vary by more than 0.2 volts. Maximum sunrise load share variation observed was 0.7 amperes. After thermal stabilization, the battery temperatures cycled between 35°F and 43°F.

### 3.6.5 Charge Current Controller (CCC) Performance

The CCC performance was very good throughout the mission. No K2 relay problems were encountered. No actual count on relay openings was available since the sunset ES record was deleted due to the requirement to minimize tape recorder cycling.

### 3.6.6 Type-40 Battery, 37°F Temperature Modification

This modification consists of a change in the temperature set point for the battery heater thermostats. Prior to SV-14, the thermostat set point had been 47°F. This modification provides for lowering the set point to 37°F in order to achieve power savings.

Calculations using normalized data from SV-13 and SV-14 indicate a power savings of 12 ampere-hours/day.

### 3.7 Tracking, Telemetry, and Command (TT&C)

#### 3.7.1 Vehicle Communication Transponder System (VCTS)

##### 3.7.1.1 Tracking

The tracking system performance throughout the mission was excellent, operating well within its required limits.

##### 3.7.1.2 Antenna Radiation Characteristics

Sets 2/PCM2 was checked weekly for the first 60 days, and monthly thereafter, to obtain signal strength data from the HLLA tracking stations with no degradation observed.

### 3.6.7 Structure Current Anomaly

Vehicle structure current was observed during horizon sensor fairing and shroud separation and also during subsatellite erection.

During the fairing and shroud separation the structure current monitor indicated current flow. The pyro bus 1 current monitor and battery 4 current monitor confirmed this flow. The current flow occurred for the duration of the booster staging timer command, WECO commands and booster flight programmer backup commands, thus indicating a continuous short.

Subsatellite erection data revealed that there was structure current during the command duration. Contact with other programs confirmed that a number of vehicles have experienced similar structure current in connection with pyrotechnic events.

Aerospace Corporation performed analyses of similar pyrotechnic devices and ascertained that electrode-to-electrode and electrode-to-structure shorts are indeed possible in ASI squibs. However, the duration of the squib shorts in the analyses is short compared to those encountered on vehicle SV-14.

To further investigate the occurrence of ASI squib shorting, an ASI squib current test was performed. This test consisted of ten pin puller squib firings in a thermal-vacuum chamber with  $10^{-5}$  Torr vacuum. One of the squibs developed an electrode-to-case continuous short.

Analysis of the fired squibs is continuing.

### 3.7.2 Telemetry

The telemetry system performed satisfactorily throughout the mission.

### 3.7.3 Tape Recorder (TR) 1 Anomaly

Tape Recorder 1 failed to start from BOT during Rev 220.2 and Rev 547. In both cases the tape recorders started with the next command. At Rev 220.2, 32 seconds of data was lost and at Rev 547, 180 seconds of data was lost. No critical data was lost. The two possible causes were identified; either the tape recorder did not respond to the command or a failure occurred in the command system. The most probable cause was a failure in the tape recorder BOT logic circuitry. Investigation is continuing. On Rev 681, the tape recorder was moved away from BOT and an operational sequence was generated to prevent returning to BOT.

### 3.7.4 Tape Recorder (TR) 2 Anomaly

During the real time operation on Rev 600, telemetry indicated a loss of 97 seconds of recorded data out of the middle of a 500 second record sequence. Analysis of the data revealed that bits in multiples of 5 were added or dropped. These bits could be identified and the data could be recovered by manual analysis. No critical data was lost during real time operation. An occasional one to three seconds of data drop-outs occurred during the real time analysis for the remainder of the flight. The analysis of this data revealed the cause to be "O" bits in the sync word, changing to "I" bits and addition/drop of 5 bits. Only one or two main frames of data were affected with each occurrence. Other cases of "O" bits changing to "I" bits occurred. No significant loss of data was experienced in real time and most of the data was recoverable.

### 3.7.5 Instrumentation

Data obtained throughout the mission indicated that excellent instrumentation performance was achieved. There were no instrumentation anomalies at lift-off.

**Top Secret HEXAGON**

### 3.6.5 Charge Current Controller (CCC) Performance

The CCC performance was very good throughout the flight. No K-2 relay problems were encountered. The K-2 relay on battery 3 opened and closed 1750 times and the battery 1 relay opened 1557 times. Batteries 2 and 4 experienced less K-2 relay openings. During solo testing a K-1 relay open was observed on battery 4 during the lifeboat battery isolation test, and K-1 relay openings occurred on batteries 1 and 3 during the K-2 bypass relay close test.

### 3.6.6 State-of-Charge Indicator (SOCI) Performance

The state-of-charge indicator (SOCI) performed within specifications limits. Allowable error is  $\pm 0.25$  ampere-hours per hour, performance was  $-0.13$  ampere-hours per hour.

## 3.7 TRACKING, TELEMETRY, AND COMMAND (TT&C)

### 3.7.1 Vehicle Communication Transponder System (VCTS)

#### 3.7.1.1 Tracking

Tracking system performance throughout the flight was excellent, operating well within its required limits.

#### 3.7.1.2 Antenna Radiation Characteristics

Weekly health tests were performed on the Block II VCTS, located in the SGLS 2 position, to ascertain transmitter signal strength and detect any recurrence of the SV-8 anomaly when a significant loss in signal strength occurred. Signal strength measurements were taken at Hula RTS throughout the flight mission and no degradation was observed.

#### 3.7.2 Telemetry

The telemetry system performed satisfactorily throughout the flight mission.

#### 3.7.3 Tape Recorder (TR)

Commencing with Rev 1923, TR-1 (type-34 Block III design) exhibited main frame sync bad (MFSB) indications. On Rev 1933 the

mission operational tape recorder was switched from TR-1 to TR-2 (type-28 Block II design). To obtain a comparison, a parallel TR-2/TR-1 record during the OA burn on Rev 1938P was accomplished. When played back, TR-2 had no MFSB indications and TR-1 had two. TR-1 was fast forwarded and, when played back, repeated the MFSBs indicating that the error was on the tape.

Analysis of the tape recorder construction and the playback data indicates that the most probable cause was particles on the tape. A new head design having a hard face (alifesil) was incorporated in this design for longer missions and "plowing" of the tape may have produced the particles. It was recommended that spooling (an end-to-end run) would clear the head of particles. This was accomplished on Revs 1992, 2170, 2637, and 2645, and the MFSB indications decreased substantially.

Tape Recorder 2 (type 28 Block II design) operated satisfactorily throughout the remainder of the mission.

#### 3.7.4 Instrumentation

The thrust chamber pressure transducer (B004) failed on Rev 1352 and is discussed in paragraph 3.3.4. Table 3-3 presents the instrumentation anomalies at lift off.

#### 3.7.5 Telemetry and Tracking (T&T) Equipment On/Off Cycles and Operating Time

Utilization of major T&T equipment throughout the flight mission (through Rev 2848) was:

BYE-9570/79

  
Top Secret

Utilization of major T & T equipment (all Block III) through deboost is as follows:

Equipment	On/Off Cycles	Operate Time (Hours)
SGLS 1	3151	293.4
SGSL 2	75	7.0
PCM 1	12570	1252.3
PCM 2	187	20.1
TR 1 (Type-35)	2857	140.1
TR 2 (Type-34)	9285	527.9

### 3.7.7 Command

#### 3.7.7.1 ~~CS~~ Extended Command System (ECS)

The Extended Command System (ECS) executed all required stored program and real time commands. The total commands stored in memory during the primary mission were 370430 of which 256803 commands were executed. Those commands not executed were erased. No anomalies were noted.

#### 3.7.7.2 ~~CS~~ Minimal Command System (MCS)

The Minimal Command System (MCS) executed all required commands during the primary mission.

#### 3.7.7.3 ~~CS~~ Remote Decoders/Backup Decoder

The remote decoders executed all required commands for each of the five recovery operations. The performance of both channels was verified for each recovery operation. The backup decoder was used in place of remote decoder-B for the RV-5 recovery operation. The backup decoder operational capability was verified during health checks and whenever it was used with the ECS.

Usage summary of the command system through Rev 2876 is as follows:

System	Total Operating Time (hours)
ECS	4250.2
MCS	4.4
RD	17.0
BUD	0.1

TABLE 3-3  
INSTRUMENTATION ANOMALIES AT LIFT-OFF

Monitor	Item	Condition
A951 A952	Shroud separation monitor	Block III design changed monitor calibration. Calibration record 37158 issued to correct the calibration tape.
B008	Primary REA 8 chamber Pressure monitor	The transducer voltage output reads high—approximately 0.16 volts (4.8 psi). Transducer operates correctly between 40 and 115 psia.
C031	Structure current monitor	Random sampling on sensor telemetry output signal provided indications of low level single sample structure current. Amplitude of transients was approximately 50 millivolts.
C042	Main bus current monitor	Whenever ECS PMU search and mid section operates, a negative spike occurs. This is an inherent condition of the ampere-hour unit.
C607 C607/C609	Forward power distribution J-box K2 relay status Forward power distribution J-box K3 relay status	Either or both monitors can respond with the application of any RV reset command.
H337	MCS word quantity monitor	Whenever the MCS is in any state other than standby/sleep and there are commands loaded in memory, the monitor may drift. This condition was introduced with the replacement of the delay line with MOSFET registers.
P235	TU bulkhead temperature	Temperature sensor failed during factory test.
X862	NiH <sub>2</sub> battery monitor	Erratic and noisy strain gage amplifier output may read any value at any time.

### 3.8 MASS PROPERTIES

A chronology of SV mass properties throughout the mission is shown in Table 3-10.

### 3.9 PREFLIGHT WINDS ALOFT LOADS ANALYSIS

Table 3-11 presents a chronological tabulation of the prelaunch winds aloft loads analysis for SV-14; the results are plotted in Figure 3-2. All parameters were well within limits at all times and no delay of launch was indicated.

### 3.10 THERMAL CONTROL

#### 3.10.1 Mid and Forward Section Lift-Off Conditions

During pre-launch operations, the ground air conditioning temperatures for the forward and mid sections were set to provide average temperatures of 73°F and 71°F respectively. The temperature levels were selected to minimize the thermal settling time required to achieve on-orbit thermal equilibrium of the primary payload and thus reduce the RV heater consumption.

The initial value predicted for the primary reference temperature,  $T_{ref}$ , based on a planned launch date, orbit beta angle range and altitude was 71°F (for actual flight parameters, the predicted  $T_{ref} = 72°F$ ).

On day 3,  $T_{ref}$  was 72.3°F; by day 8,  $T_{ref}$  was 73.1°F; on day 32,  $T_{ref}$  was 71.6°F. The orbit average temperature of the two mid section compartments similarly rose in the early days of the flight, probably due to the heavy payload activity during this period.

~~Top Secret HEXAGON~~

### 3.8 MASS PROPERTIES

A history of SV mass properties throughout the flight is tabulated in Table 3-4.

### 3.9 PRELAUNCH WINDS ALOFT ANALYSIS

The results of the SV-13 loads analyses of prelaunch winds aloft are plotted in Figure 3-3. The analyses are based on Rawinsonda and Jimsphere balloon soundings taken on 26 and 27 June 1976. All parameters were well within limits at all times, and all recommendations were "go--continue count" and finally "go for launch."

### 3.10 THERMAL CONTROL

Flight data indicated that the average temperatures of the aft, mid, and forward sections were well within design limits. There were no thermal anomalies.

The flight temperatures of the NAVPAC (-Y pallet) and the NiH<sub>2</sub> battery (+Y pallet) remained within design limits throughout the flight. The miniature electrostatic accelerometer (MESA), which is a functional part of the NAVPAC module, is attached to the +Z surface of bay 4 rather than the -Y pallet. The MESA temperatures were within limits throughout the flight; however, the orbital temperature swings were larger than desired (approximately 26°F from the minimum to maximum levels). A thermal shield addition has been designed to cover the MESA on future vehicles which will reduce the orbital temperature swings.

TABLE 3-4

BYE-9570/79

3-16

~~Top Secret~~

Approved for Release: 2025/07/25 C05128734

3.10.2 Mid Section, Forward Section and MCM Orbit Temperatures

~~Tables 3-12 and 3-13 present orbit average temperatures for critical vehicle parameters for Rev 506, orbit beta angle = 22°. The data was derived from vehicle temperature monitors using methods described in detail in the respective Interface Control Documents. The vehicle temperatures and temperature differentials were well within allowable limits.~~

3.10.3 Aft Section Thermal Performance

The aft section equipment configuration and thermal control design of SV-14 are essentially identical to those of SV-13. The only significant difference is that battery heater set points were lowered by 10° F for SV-14, as a power-saving design change. Flight temperatures are similar to those of SV-13 with the exception of the lower battery temperatures, and no thermodynamic anomalies were noted.

All equipment operated well within design limits and battery temperature was controlled satisfactorily by the new lower heater setting.

3.10.4 Pallet Experiments

The +Y and -Y Pallet payload temperatures are tabulated in Table 3-15. These temperatures are the orbit average values and were well within design limits. The temperature data indicated that the thermal control design adequately controls component temperatures.

PERFORMANCE EVALUATION TEAM  
REPORT NO. 1213

## SECTION IV

### PAYLOADS

#### 4.1 PANORAMIC CAMERA SYSTEM

##### 4.1.1 Camera Operations and Performance

Mission 1213 represented a number of significant and unique milestones:

a. This was the first of the Block III design, incorporating several system improvements with increased reliability.

b. Both cameras demonstrated the capabilities to utilize the new generation of thinner-base films. As a result, on future missions the thinner-base SO-208 will replace 1414 as the primary film, resulting in an increase of approximately 16% in the film supply. Both cameras also demonstrated the capability to successfully utilize the new, special film types (SO-460, SO-464, and 7011).

c. This was the first mission in which the film path was purposefully maintained above a minimum pressure (0.55 psi) to minimize image degradation. The required pre-pumping of the path to this minimum was performed 73 times during the mission, consuming an additional 1.6 lbs of pneumatics.

d. The active photographic mission duration of 175 days was the longest to date. The previous maximum was Mission 1212 at 155 days.

e. More operations were executed than on any previous mission. The total of 1068 operations exceeded the Mission 1212 record of 1048.

##### 4.1.2 Camera Data

Panoramic camera data are summarized in Table 4-1.

## 4.1.3 Camera Operation

Operational photography began on Rev 7, but was temporarily suspended after Rev 13 because of an anomaly in the shutter open/close logic during Ops 6, 7, and 8. The randomly recurring failure caused the shutter to open in the fail-safe mode and to close in an erratic timing pattern. The failure was successfully circumvented by switching to SCC Block II, with a return to normal operations on Rev 39.

On Rev 107 Op 48, there were two instances where Forward camera frame reference times coincided with shutter open rather than the first five degree mark. This was deemed to be a recurrence of an infrequent, sporadic phenomenon seen on past vehicles having no significant impact on operational performance.

~~Top Secret~~

~~Top Secret HEXAGON~~

On Rev 124 Op 56, the Forward camera first frame reference time did not appear on telemetry and the DIU counter did not increment. Subsequent data analysis showed an absence of the frame 1 request pulse caused by the OB reaching constant velocity too late to allow request pulse gating from the SCC. A change to the start-up command sequence was implemented forcing the OB to be commanded on one cycle earlier. The problem was not seen for the remainder of the mission.

Based on the predicted stack-height clearance remaining, four short ops were planned just prior to the recovery of RV-1. At the completion of the rewind on Op 202 Rev 563, the Forward camera "TU-Exceeds" switch initiated an ESD, precluding the execution of the remaining three ops. Normally, as the take-up stack approaches its outer limits, the raising of the builder roller during rewind will trigger the "TU-Exceeds" switch, but the associated IESD logic disables the monitor during rewind. However, for this op, the electrical/mechanical hysteresis in the switch was sufficient to inhibit the resetting of the switch as the builder roller lowered at the completion of rewind. At that point, the logic was re-enabled and sensed the triggered switch thus initiating the ESD. These switches will be disabled on future systems.

Camera operations were again interrupted on Rev 791 Op 274 by an ESD initiated by a momentary loss of the seal door verify signal. The phenomenon occurred again on Rev 971 during an attempted camera start-up, precluding execution of a nested pair of ops. Because of its momentary nature and low incidence of occurrence, corrective action was not taken. The problem did not recur.

During Rev 2334 Op 838, the film path vent valve failed to open at the designated pressure. This anomalous condition continued throughout the remainder of the mission. The build-up of potentially catastrophic chute pressure was avoided by active management of operations and pneumatics-ON time.

The active photographic mission was terminated with RV-4 recovery on day 175 following depletion of both film supplies. The Forward supply was depleted on Rev 2840 Op 1070. This was also the last operation on the Aft camera, its supply depleting during the final CV which pulled the film tails onto the take-up.

~~Top Secret~~

~~Top Secret HEXAGON~~

Figures 4-1 through 4-6 present various mission histograms based on actual film usage. These histograms are representative of typical Hexagon missions. Figures 4-1 and 4-2 depict film usage in feet and frames, respectively, as functions of scan width, scan center, and scan sector. Figures 4-3 and 4-4 present histograms of exposed film footage as a function of vehicle altitude and latitude. Figures 4-5 and 4-6 illustrate the distribution of photographic coverage in terms of land mass (area) and fully framed targets, respectively, as functions of scan sector.

#### 4.1.4 Focus

Analysis of the through-focus engineering photography, using VEM, optical power spectrum, and subjective data, indicated that the prelaunch focal plane settings on both cameras were less than optimum. The Forward focal plane was retreated four micrometers and the Aft retreated six micrometers.

~~Top Secret HEXAGON~~

#### 4.1.5 Film Synchronization

Mission 1213 nominal OAAA settings for 1414 film are summarized as follows:

<u>Camera</u>	<u>Direction</u>	<u>1213-1</u>	<u>1213-2</u>	<u>1213-3</u>	<u>1213-4</u>
Forward	In-track	0	-2	-2	-2
	Cross-track	-2	-2	-2	-2
Aft	In-track	0	-1	-1	-1
	Cross-track	2	2	2	2

Analysis of smear slit imagery from OAAA engineering operations resulted in changes to the initial settings. Smear variability was determined to be within the system design goal.

#### 4.1.6 Photographic Image Quality

Overall image quality on both the Forward and Aft cameras for the entire mission ranged from good to poor, with the majority rated fair. The Aft camera image quality was considered slightly better than that of the Forward camera. The poor imagery was typified by heavy haze and clouds.

Mean VEM resolution was 154 lines/mm on the Forward and 157 lines/mm on the Aft camera. Ground resolved distances (geometric mean) on 1414 film, as determined from 9 CORN tribar acquisitions, ranged from 2.08 to 2.85 feet with varying format location and contrast. Two acquisitions each with SO-130 and SO-255 averaged 4.9 feet and 4.1 feet, respectively. There were also 9 CORN tribar acquisitions with SO-208 film, indicating GRD values of 2.45 to 3.24 feet. The tribar target readings acquired with the special films (SO-460, SO-464, and 7011) ranged from 1.96 to 2.95 feet. The overall quality of Mission 1213 was considered to be somewhat less than that of the previous two missions.

#### 4.1.7 Exposure

Microdensitometric analysis of urban/industrial imagery throughout Mission 1213 indicated nominal exposure for 1414, whereas the special black-and-white films in segment 1213-4 were generally overexposed with regard to their respective aim densities. Subjectively, all films appeared adequately exposed except for 7011 at solar.

~~Top Secret~~

~~Top Secret HEXAGON~~

elevations of less than 10°. This was the result of the smear exposure trade-off bias used for the first time in the 1213 exposure algorithm.

The exposure of the early mission SO-255 and SO-130 acquisitions were judged subjectively to be underexposed. An increase of 3 counts (0.01 log E) and 4 counts (0.13 log E) in the exposures of SO-130 and SO-255, respectively, resulted in satisfactory exposure for the remainder of the mission.

#### 4.1.8 Engineering Tests

Twenty-two engineering tests were planned for Mission 1213. Nineteen of these tests were at least partially accomplished and produced satisfactory results; the others were deleted because of unfindable requirements or lack of appropriate acquisition opportunities. Three tests performed on Mission 1212 were eliminated from this mission, and eleven new engineering requirements were identified. Several of the new tests pertained to the evaluation of the special films included in this mission. Table 4-2 summarizes the objective and status of each test.

#### 4.1.9 Processing and Reproduction

The core locking pins were in place on all mission segments. Initial inspection of RV-2 revealed significant amounts of moisture on the external structure due to the water recovery. Subsequent inspection showed the interior to be dry with no damage to the film stacks. Although there were some changes in the processing equipment used, the system production curves and standards remained unchanged from previous missions.

19 Van acquisitions	Evaluate atmospheric effects on image quality	Accomplished in RV-1, RV-3, RV-4
24 Special targets (SO-130)		Deleted - No targets defined
25 Through-exposure (SO-208/460/464/7011)	Establish exposure/quality relationship for special films	Completed for SO-208/464 only in RV-4
26 Orbital/sensitometry	Evaluate on-orbit sensitometry	Completed in RV-1, RV-4
27 Parabolic dish mensuration	Test mensuration programs	Accomplished in RV-3
28 Diffusion model	Study viscous processing diffusion effects	Accomplished in RV-3
29 Bar XC (1414 & special films)	Measure film distortion characteristics	Accomplished in RV-2, RV-4 (types 7011 & SO-464 not completed)
30 Low light level	Evaluate low light level processing techniques	Requirement deleted

NPIC's evaluation of the black-and-white duplicate positives from Mission 1213 show them to be slightly lower in quality than those of previous missions. The resolution losses do fall within the expected bounds of resolution transfer characteristics and, hence, do not constitute a significant problem.

~~Top Secret~~

~~Top Secret HEXAGON~~

#### 4.1.10 Exploitation Suitability

The overall average NIIRS rating of Mission 1213 was 3.6, which is 0.4 NIIRS lower than Mission 1212 and 0.6 NIIRS lower than Mission 1210. This average is based on a reduced number of ratings because of changes in the read-out requirements. The lower performance level was not attributable to scan angles, vehicles altitudes, or solar elevations, but did show some preference to geographic area.

Analysis of color imagery indicates PI suitability of SO-255 and SO-130 from Mission 1213 to be similar to those film types from previous summer missions. These films are very useful for agricultural assessments, economic intelligence in mining and shipping operations, and monitoring possible nuclear weapons development in the third world areas.

A special evaluation of the new films was performed to determine whether they have the potential to provide an improvement in NIIRS values over the standard 1414/SO-208 emulsion. The evaluation was designed to eliminate the influence of altitude, target type, scan angle, and solar elevation. The overall results indicate a significant confidence that the 7011 (SO-315) and SO-464 films will provide better quality imagery than the present standard emulsion.

#### 4.2 MAPPING CAMERA SYSTEM

##### 4.2.1 Operations and Performance

The Mission 1213 mapping camera system operated on 201 revs between Rev 3 and Rev 1816, with RV-5 recovery on Rev 1825. A total of 2115 frames were exposed in the terrain camera and a corresponding number of frame pairs in the stellar camera. This total includes 22 frames of film type 3401 and 60 frames of film type 1414 in the terrain camera for in-flight calibration and ultra-thin base film image quality evaluation.

Post flight analyses conducted at the processing site, the contractor facility, and the Defense Mapping Agency Topographic Center (DMATC) have shown that mission objectives were met with a high level of success, and that this terrain camera produced image quality and resolution comparable to past mapping camera missions. Image analysis performed on 1414 film showed no significant differences between 3414 and 1414 films. An adequate distribution of sixth magnitude stars was acquired on the stellar frames, and ancillary data generated by both units were acceptable.

~~Top Secret~~

~~Top Secret HEXAGON~~

Weather during photographic operations showed improvement over Mission 1212. Approximately 35% of all frames were 90-100% cloud free.

Table 4-3 summarizes significant mapping camera activities.

TABLE 4-3

## SUMMARY OF SIGNIFICANT MAPPING CAMERA SYSTEM ACTIVITIES

<u>Rev</u>	<u>Activity</u>	<u>Event</u>
-	Ascent	No anomalies

## 4.2.2 Mapping Camera System Data

Mapping camera system data for Mission 1213 is presented in Table 4-4.

TABLE 4-4

## MAPPING CAMERA SYSTEM STATISTICS

<u>Element</u>	<u>Camera</u>		
	<u>Terrain</u>	<u>Stellar</u>	
		<u>+Y</u>	<u>-Y</u>
Focal length (mm)	304.779	252.878	252.324
Filter type	W-12	none	none
Reseau S/N	020	041	040
Lens S/N	009	018	017
Supply spool S/N	065		105
Supply film weight (lbs)	56.72		10.07

## Film data:

Terrain camera: Film type (feet) 3414 (3270)/MCD(2)/3401(30)1414(100)

Stellar camera: Film type (feet) 3400(1872)/SO-344(230)

~~Top Secret~~

~~Top Secret HEXAGON~~

#### 4.2.3 Image Quality

The majority of the image quality from the terrain camera was good to excellent and appeared consistent throughout the flight. The average resolution derived by VEM analysis was 94 lines/mm. Target imagery of the Ft. Huachuca resolution range was not available for evaluation on this mission. Stellar imagery was good for both units. On evaluated frames, each stellar camera recorded 6th magnitude and fainter star images.

#### 4.2.4 Exposure

Density measurements made at the processing facility indicated that the exposure levels were slightly higher than nominal. An adjusted exposure algorithm for 1414 film and equivalent Wratten 12 filtration will be implemented on Mission 1214.

#### 4.2.5 Thermal Profile

Following on-orbit stabilization, the terrain camera average temperature was steady at 74.0°F and the stellar cameras at 74.5°F.

#### 4.2.6 Pressure Profile

Average film path pressure stabilized at 16 micrometers. A maximum of 17 and a minimum of 16 micrometers were recorded during the flight.

#### 4.2.7 On-Orbit Calibration

In addition to the preflight calibration data, two additional calibration steps--range and stellar, which are distinctly separate operations--are conducted in-flight.

Range calibration is conducted while operating the camera in the normal mode over a ground range containing accurately measured control points. A typical range is the Bar XC located in the Arizona/New Mexico area. Stellar calibration, conducted at the end of the S/T mission, is accomplished by inverting the vehicle to simultaneously give each of the S/T lenses a view of the starfield.

~~Top Secret~~

4.3.1 The Navigational Package (NAVPAC) flight unit operated without failure for the entire mission. Doppler frequency data collected was of high quality.

The NAVPAC uplink antenna deployment data gave indication of less than full deployment. Although subsequent analysis confirms this situation, the data being analyzed is suspect. In-house testing procedures for future systems have been modified to provide more confidence in the operational deployment data. The antenna was successfully operational.

The Miniature Electronic Static Accelerometer (MESA) orbital cyclic temperature variations experienced on SV-13 were reduced on SV-14 by the addition of a heat shield to protect the MESA from direct sun. This maintained the baseplate temperature at  $84^{\circ}\text{F} \pm 5^{\circ}\text{F}$  which was functionally acceptable. However, to reduce the  $\pm 5^{\circ}\text{F}$  excursion, SV-15 will include heaters to maintain the baseplate temperature at  $105^{\circ}\text{F}$  with minimal excursion. The MESA X and Y axis noise, present on SV-13 was also present on SV-14. To correct this problem on SV-15, low noise preamplifiers will be added and full scale limits on all three axes will be decreased.

Some of the experiment results were as follows:

- o Dual Tracking Loop (DTL) calibrations were successfully accomplished.
- o A NAVPAC/MESA power-down - power-up sequence was performed to obtain MESA start up data.

With the MESA off, two high rate data storage tests were conducted. Also with MESA off, two direct read-out tests were conducted. One utilized transmitter 1 and the other utilized transmitter 2. Both sets of tests were successful.

#### 4.5 DOPPLER BEACON SUBSYSTEM (DBS)

The Doppler Beacon Subsystem (DBS) performed normally in support of the longest mapping camera mission to date (118 days). The primary transmitter, oven and oscillator combination was used throughout the mission, which provided good signal strength (100 - 125 dBm) on both doppler frequencies.

At the conclusion of the mapping camera's mission, all the redundant DBS commands and functions were exercised without incident. The SV command and telemetry support was satisfactory. No anomalies were reported.

~~Top Secret HEXAGON~~

### 4.3 NAVPAC, MESA, AND DOPPLER BEACON SYSTEMS (DBS)

4.3.1 The NAVPAC flight unit operated without failure for the entire mission. Doppler frequency data collected by the NAVSAT receiver portion of the hardware was of high quality. One day's worth of data was lost after a command computer failure at Boss prevented the sending of a tape recorder stop and reset commands at the end of a readout. Subsequent units have been modified so that the logic is reset automatically when beginning of tape is reached.

The MESA system produced questionable data for two reasons:

a. The thermal environment induced short duration anomalies and bias variations about the orbit. For future missions, a thermal shield is to be placed over the MESA assembly.

b. Acceleration through orbit adjusts (OA's) were not measured because the 2-second delay time in the automatic instrument range selection was too long. This has been reduced to .25 seconds and the measurements have been successfully read in ground tests.

The following experiments and calibrations were successfully completed.

a. The 36-hour warm-up of the NAVPAC primary oscillator was more than adequate to reach the required frequency stability.

b. Eight dual tracking loop calibration tests of twelve hours duration each were conducted to evaluate the relative performance of the three receivers.

c. One twelve-hour test of high speed telemetry data (MESA off, mode 1) was run to evaluate short term behavior of the receiver system.

d. Various modes and back-up equipment were tried and the hardware operated as expected.

4.3.2 The doppler beacon system (DBS) performed normally in support of the longest mapping camera mission to date (113 days). The primary transmitter, oven, and oscillator combination was used throughout the mission, which provided good signal strength (100-125 db) on both doppler frequencies. At the conclusion of the mapping camera's mission, all the redundant DBS commands and functions were exercised without incident. The SV command and telemetry support was satisfactory; no anomalies were reported.

~~Top Secret~~

~~Top Secret HEXAGON~~

#### 4.2.8 Summary of Anomalies

The only mapping camera anomalies occurred on Revs 91 and 93. The redundant stellar pressure monitor indicated three erratic pressure signatures. The primary pressure monitor indicated normal operation. Engineering analysis indicates the erratic signal was attributed to the telemetry microswitch. It caused no operational problem and did not recur.

#### 4.2.9 Exploitation Suitability

Technical analysis of Mission 1213 imagery by the DMA Post Flight Analysis Team included a comparison of the photography with system specifications. As a result of their instrument measurements and various other metric evaluations, it was determined that the system satisfied all critical performance requirements.

#### 4.2.10 Processing and Reproduction

The RV arrived at the processing site in good condition at 1000 hours EST, 18 October 1977. Both film spools were also in good condition.

Defilming was accomplished on 18 October, and no static discharges or film sticking were noted during the presplice operation.

The terrain and stellar records were processed without incident. The 3401 and 1414 portions of the terrain record were processed separately.

A 52-foot strip of stellar record was removed and processed as a test to assess fog levels.

Optical titling was accomplished on 95% of the terrain 3414 film. The stellar record was 67% optically titled. The remaining were hand-titled.

All duplicate copies were printed on the Kingston printers using the Actinic-Butterfly Contrast Control (ABCC) technique. Duplicate positives of the 3414/1414 terrain films were prepared on SO-192. Duplicate positives of the 3401/SO-284 terrain films were prepared on Kodak Aerographic Duplicating Film (Estar base). Duplicate positives of the stellar 3400/SO-344 film were prepared on SO-284. All duplicate negatives were prepared using Kodak Direct Duplicating Aerial Film (Estar base) 2422.

~~Top Secret~~

### S77-2 Pallet Experiment

The S77-2 Pallet system performed successfully for 172 days in orbit except for a ROCA failure late in the mission and an SRE/TRE anomaly on day 57. Approximately 728 hours of data were read into the pallet tape recorders and subsequently read out and transferred to SAMTEC (the SAMSO-designated flight data processing agency). There were several interruptions in the S77-2 system tasking, caused by conflicting host vehicle activities and power shortages; however, all of the objectives of the S77-2 flight requirements and operations plan including coverage of primary SRE/TRE special interest areas were met. Based on observation of the pallet status telemetry, which was monitored continuously throughout the flight, it was concluded that all contractor, GFE and experiments operated normally, except for the ROCA and the SRE mirror drive system. All S77-2 data tapes, command listings and orbital vectors have been sent to the appropriate agencies (SAMTEC, AFTAC and SAMSO) for merging with and to facilitate processing of pallet downlink data.

Some of the more pertinent results were as follows:

- o Seven complete and one partial twenty day tasking cycles were completed during the mission.
- o Successful tests of the pre-modulation filter bypass and the tape recorder bypass modes were conducted.
- o A horizon scan test was conducted for CRL 246 during solo.
- o Special coverage of Kwajelelin during cooperative sounding rocket launches was made for the benefit of the NRL 607 experiment.
- o The pallet thermal control system performance was essentially as predicted.

~~Top Secret HEXAGON~~

#### 4.5 NICKEL-HYDROGEN (NiH<sub>2</sub>) BATTERY PALLET EXPERIMENT

All the NiH<sub>2</sub> battery flight tests were successfully completed. The experiment demonstrated that the battery could survive the space environment and could support both a 1 amp operational NAVPAC/MESA load (127 days) and a 5 amp simulated load (52 days). The battery was charged to a K2 level (90% state-of-charge) 141 times and was discharged using the load bank 26 times with expected results each time.

The only operational problems to arise were:

a. Early in the flight, an error was discovered in the flight support data base that caused the battery bus to voltage to appear low.

b. After the host vehicle began supplying a near continuous low current charging the battery, the NiH<sub>2</sub> battery temperature started rising. Since the battery was at a high state-of-charge (approximately 90%), most of the charging current was converted to heat. By switching the NAVPAC/MESA load (1 amp) back to the host vehicle bus and using the load bank to periodically discharge 5 amps for 3 revs, the battery temperature limits were maintained.

~~Top Secret~~

~~4-8~~ SUBSATELLITE  
46

A classified Subsatellite (SSU-32) was carried into orbit on the -Y side of SV-14. Total weight of the SSU system was 649.3 pounds of which 590.9 pounds separated from the SV. Separation of the SSU occurred at SV Rev 13.5 at 2° South latitude on a descending node. The SV yawed -18.6 degrees for the SSU separation event. The SSU went on to achieve its intended orbit and function.

REPORT NO. 1213

## SECTION V

## REENTRY VEHICLE SUMMARY

## 5.1 SUMMARY

Recovery statistics are shown in Tables 5-1 and 5-2. All reentry vehicle (RV) on-orbit and reentry events occurred as planned, and the RV flights followed the predicted trajectories. All five flights were successfully retrieved near the PIP. ~~Four aerially and one from the water surface~~ <sup>A</sup> **AERIAL**

All payloads were recovered in good condition with no deficiencies attributable to the RVs. All subsystems performed satisfactorily and met all mission requirements. ~~On RV-2 the target cone did not properly inflate and recovery was made using the back-up water recovery mode.~~

## 5.2 MARK VIII REENTRY VEHICLE SYSTEMS

All on-orbit functions for the Mark VIII (pan camera) RVs were normal and occurred on time. The SV provided a satisfactory pitch angle for each RV separation. All other SV/RV interface functions were nominal. The RVs were adequately spin stabilized during the vacuum coast phase and aerodynamically stable during the atmospheric phase of the reentry trajectory.

All subsystems performed satisfactorily with the following ~~two~~ exceptions:

Recovery system target cone: on RV-2 the target cone did not deploy which precluded aerial retrieval and resulted in a surface recovery. Postflight investigation indicated that during parachute deployment some of the geodetic lines, which are a part of the target cone design, wrapped around the cone pack preventing proper deployment. Analysis indicates that the system design concept does involve a minor threat rather than this being a unique deficiency of the RV-2 recovery system. Even though the present recovery system threat is considered low, changes are being incorporated to further reduce the threat.

SMDC line separation: during postflight inspection, deposition on recovered components indicated that ~~the~~ <sup>several</sup> SMDC lines had separated from connectors during RV/SV separation. In all cases,

bolt fracture and SMDC line detonation occurred normally. This event has occurred on previous flights and no further corrective action is considered necessary.

### 5.3 MARK V (STELLAR/TERRAIN) RECOVERY VEHICLE SYSTEM (RV-5)

RV-5 (S/N <sup>1810</sup>1809) was successfully recovered on Rev <sup>1902</sup>1825 after <sup>117</sup>113 days. Recovery statistics are shown in Table 5-2. All RV subsystems performed normally. The SV provided a satisfactory pitch angle after a yaw reverse and all other interface functions were nominal.

The miss distance between the predicted impact point (PIP) and the estimated point of parachute deployment (EPPD) was calculated to be <sup>5.4</sup>3.87 NM long and <sup>13,200</sup>0.70 NM east of the ground track. The capsule was recovered at 13,500 feet on the first pass.

The only exception to an otherwise normal recovery sequence was after the execution of the trim and seal sequence (closure) when one of two microswitches monitoring the seal door closing remained open. It registered the proper position after approximately 150 seconds. ~~Postflight examination revealed that the monitor had an inorganic deposit on the external surface of the switch plunger.~~

## SECTION VI

## OPERATIONAL SUPPORT

## 6.1 SATELLITE CONTROL FACILITY (SCF)

The performance of the SCF in support of Mission 1213 was excellent. This was the longest low altitude satellite mission in Air Force history. The 180-day lifetime exceeded the previous mission record by 14%. The 1,214 command messages generated during the flight is a first for this program. The 2,914 rev duration led to a significant increase in nearly all resources. Several equipment and operational problems were encountered; however, the problems caused minimal impact to the overall mission. Command message generation and transmission and downlink TM reception and processing supported the operation satisfactorily.

## 6.1.1 Preflight Readiness

Hardware and software interfaces were validated during four readiness exercises. Development rehearsals were conducted during the periods 24-28 January, 21-25 March, and 24-27 May 1979. A 48-rev dress rehearsal was conducted during 14-17 June 1979. Activities included day one testing, normal flight operations per the profile, and telemetry playbacks for the first five revs.

## 6.1.2 Orbital Operations

A nominal one-rev load cycle for the payload was employed during the mission. A total of 2356 command messages were planned, of which 1214 were generated and 1189 were actually loaded into the vehicle. The major reasons for nongeneration of planned command messages was that no payload selections occurred within the new message generation space. The major causes for rejection of generated messages were (1) vehicle problems, (2) station problems, and (3) message generation/cycle-related problems. One dedicated CDC 3800 computer was used throughout the operation; a second computer was used as required. Approximately 5,910 computer hours were used for a mission average of 32.8 hours per day. This resulted in the use of 1.50 computers per day. The Varian 73 (EBC), CDC 160A, and 1230 MTC computers were also successfully utilized. There were 2,959 contacts made with the SV through the remote tracking stations. The totals for each station are listed below:

~~Top Secret~~

~~Top Secret HEXAGON~~

inability to properly strip telemetry data from the bird buffer tape for use by MPR. The second problem concerned reporting of zero data for a panoramic camera health check which could not be properly processed by the user agency. Corrections to both problems were successfully made.

TE 0515

## SECTION 4

## ELECTROMECHANICAL PERFORMANCE

Reviewing electromechanical acceptance data and its correlation to acceptance photo data confirms the system has demonstrated compliance with all performance requirements. No out-of-specification conditions exist.

## 4.1 EMERGENCY SHUTDOWN

Verification of controlled system shutdown to both internally and externally commanded ESDs was performed during assurance and acceptance testing. For all ESDs, the system shut down properly and the expected diagnostics were present.

## 4.2 RV TRANSFER

Functional tests verified normal operation with an AGE take-up sequentially cabled to each of the four RV locations in accordance with the test parameters of Table 2-1 (Format Test Matrix) of CEI Specification SI 621-0090-0001.

## 4.3 CAGING

Looper and Supply Assembly caging tests were performed during horizontal and vertical baseline testing. Acceptance testing, which is performed in the vertical position, consists of cage, uncage, cage and backup uncage sequences. All sequences were properly executed and all performance requirements were met. After completion of acceptance testing, the supply and loopers were caged and verified in preparation for delivery to the integrating contractor.

## 4.4 NEGATIVE CONSTANT VELOCITY TESTS

The NCVU operation in TU ONLY and SU ONLY was verified during assurance tests; the NCV mode was verified during vacuum acceptance tests. And, in all tests, the tracking and electromechanical performance was proper.

~~Hx TOP SECRET~~

~~TOP SECRET~~

TE 0515

#### 4.5 SCAN MODE

All scan centers and scan angle lengths were tested successfully during the horizontal baseline format tests. The off center scan tests and the operational mode verification tests, which were conducted in vacuum, also met all performance requirements. In each, evaluation of electromechanical data includes verification of phasing, shutter open and close time, and associated EM signals. Actual frame lengths are measured on the film exposed during the format tests.

#### 4.6 START/STOP TIMES

All measured start/stop times as required by the CEI specification were within specification. For the  $V_x/h = 0.052$  runs, the start/stop times range from 66 to 67 seconds thus meeting the CEI requirement of being less than 71 seconds.

#### 4.7 SLIT WIDTH

The measurement of slit width versus slit command is within specification (See Table 4-1 for calibration of measured width and telemetered width versus commanded width.)

#### 4.8 OPTICAL BAR SCALING

Optical bar velocity calibration was performed in both Blocks I and II of the SCC. The calibration (Table 4-2) shows that the actual velocities at all  $V_x/h$  commands tested tracked the theoretical value within one percent of the maximum commandable velocity (0.00054 rad/sec). At no time during system testing did the optical bars exceed the  $\pm 1$  percent velocity limit set in the SSTC limit check.

#### 4.9 FINE PATH PERFORMANCE

The following parameters, evaluated to monitor the performance of the fine film path, were within specification during the acceptance runs delineated by the CEI specification:

Phase Lock Error + $\Delta P_f$ (Theoretical)	Skew Angle Modification ( $\psi$ )
Fine Tension	Metering Capstan Tachometer
OB Summed Error	$\Delta P_f$ (Theoretical) - $\Delta P_f$
Metering Capstan Summed Error	Film to Bar Sync (FBS)
Photo Mode Error (PME)	

The limit checks and the percentage of samples within the limits for the metering capstan summed error and the film-to-bar synchronization signals are shown in Table 4-3.

The metering capstan summed error has been evaluated by comparing each CEI-required run to a particular reference run. At each temperature, a reference run is designated for each different  $V_x/h$ . A small percentage of metering capstan summed error samples during P Mode are examined to determine the mean and two-sigma for the run, e.g. at  $V_x/h=0.052$ , the program examines 15 samples at each of the three collimator positions or 45 out of 636 (about seven percent) and calculates the mean and two-sigma. A delta of 0.04 inch/sec is added to establish the acceptance window for all the other samples of the reference run and all the P-Mode samples of any other  $V_x/h=0.052$  run at the same temperature. As can be seen from Table 4-3, all the runs have greater than 99 percent of the samples falling within the reference window.

#### 4.10 FOCUS

Focus for the fwd and aft cameras was calibrated at nadir. Shown at temperatures of 47°F, 70°F and 93°F are three point calibrations (Figures 4-1 and 4-2) between the focal plane position as read from the telemetry diagnostic and the corresponding focal plane command. Theoretically, this is a one for one linear relationship resulting in a straight line of 45 degree slope, as shown. Actual data measurements are plotted with (+).

In addition, at each of the three commanded focal plane positions, the film line targets were examined and the average (in-track and cross-track) point of best focus determined. As expected, for this relationship, a horizontal line plot should result because moving the physical focal plane should not affect

Operate	65	54	61	60	61	58
Stop	57	49	53	57	59	55

#### 4.12 DRIVE AND METERING CAPSTAN FREQUENCY SPECTRA

Data obtained during a single frame of CEI run 105, an 00AA calibration run, are plotted in Figures 4-3 and 4-4 (Fourier spectra for all three capstan summed errors of both cameras) and Figures 4-5 and 4-6 (time based correlations of each signal with film-to-bar synchronization). The sample frame was taken with both skew and velocity commands set at zero; CEI run 105 was with a RADX of 0.052 with IMC enabled.

The Fourier plot of the metering capstan summed error for the FWD camera shows the three typically predominant frequencies. The lowest of these (~63 Hz) represents a once-per-revolution disturbance emanating from the

~~TOP SECRET~~

~~TOP SECRET~~

TE 0515

metering capstan; the highest ( $\sim 126$  Hz) represents the metering capstan's true twice-per-revolution disturbance. The middle frequency ( $\sim 104$  Hz) represents a once-per-revolution disturbance caused by a 0.6-inch roller in the platen assembly. None of these frequency components, however, represents a potential performance problem.

## 5.2 OPERATING CONSTRAINTS

There are no unique operating constraints relating to operation of S/N 015, other than those listed in the HSSOP document. Testing done prior to 26 September 1974 was conducted under the constraints of the HSSOP document, Revision AS, and PM-1428, Revision C.

## 5.3 MASS PROPERTIES

Compliance with the mass properties ICD requirements is shown in Table 5-2. The total weight and products and moments of inertia for an empty and full midsection are tabulated in Figures 5-1 and 5-2. Figure 5-3 illustrates the coordinate axes and notation system.

## 5.4 ICD COMPLIANCE

S/N 015 meets all applicable ICD requirements.

## SECTION 6

## SENSOR SUBSYSTEM ON-ORBIT PERFORMANCE PREDICTION

The object of the on-orbit performance prediction computation is to predict the camera system's resolution capability on orbit, based on Chamber A measurements, Chamber D measurements or budgeted values of errors where applicable. The Performance Prediction Program (PERF) is designed to create, for each location considered in the photographic format, 500 samples whose statistics represent actual system performance. For each sample, the amounts of defocus, in-track smear, and cross-track smear are determined by means of a random number generator. In-track and cross-track resolutions are computed by intersecting the resulting transfer functions with the film AIM (Aerial Image Modulation) curve.

The average values of the resulting geometrical mean resolutions for the two cameras at 47°F, 70°F, and 93°F at nine locations in the photographic format are shown in Tables 6-1 through 6-6. The major data inputs to PERF were as follows:

a. Image Motion Errors

1. Mechanization Errors - Chamber A sync-flash measurements
2. Vehicle Induced Errors - budget
3. Residual Errors - computed fixed knowns

b. Defocus Errors

1. Dynamic Defocus - Chamber A line target measurements
2. Thermal Defocus - Chamber A line target measurements
3. Flight Focus Calibration - budget

~~TOP SECRET~~
